Conclusions

ADE singularities

- ▶ As a first example of the difficulties in globalizing, consider the ADE singularities.

ADE singularities

- ▶ As a first example of the difficulties in globalizing, consider the ADE singularities.
- ▶ These can be studied locally as $X_0 = \mathbb{C}^2/\Gamma$, with their resolutions given by ALE spaces X . Much can be learned about the rôle which such singularities play in string vacua by studying $X_0 \times M$ or $X \times M$. The presence of the singularity leads to a nonabelian gauge group in IIA string theory, M-theory and F-theory.

ADE singularities

- ▶ As a first example of the difficulties in globalizing, consider the ADE singularities.
- ▶ These can be studied locally as $X_0 = \mathbb{C}^2/\Gamma$, with their resolutions given by ALE spaces X . Much can be learned about the rôle which such singularities play in string vacua by studying $X_0 \times M$ or $X \times M$. The presence of the singularity leads to a nonabelian gauge group in IIA string theory, M-theory and F-theory.
- ▶ However, globalizing these singularities is a different matter. If one asks for a Calabi–Yau 2-fold (i.e., a K3 surface) with such a singularity, then the rank of the gauge group is bounded by 19.

- ▶ As a first example of the difficulties in globalizing, consider the ADE singularities.
- ▶ These can be studied locally as $X_0 = \mathbb{C}^2/\Gamma$, with their resolutions given by ALE spaces X . Much can be learned about the rôle which such singularities play in string vacua by studying $X_0 \times M$ or $X \times M$. The presence of the singularity leads to a nonabelian gauge group in IIA string theory, M-theory and F-theory.
- ▶ However, globalizing these singularities is a different matter. If one asks for a Calabi–Yau 2-fold (i.e., a K3 surface) with such a singularity, then the rank of the gauge group is bounded by 19.
- ▶ In this case, it is possible to explicitly describe which gauge groups can occur (cf. [DRM, Invent. Math. 75 \(1984\) 105–121](#)).

- ▶ Suppose one wanted to do some kind of statistical analysis of gauge groups in this context. Based on the local analysis, one would likely conclude that groups of type $SU(n)$ or $SO(2n)$ occur with probability 1, and the groups of type E_6 , E_7 , and E_8 occur with probability 0.

- ▶ Suppose one wanted to do some kind of statistical analysis of gauge groups in this context. Based on the local analysis, one would likely conclude that groups of type $SU(n)$ or $SO(2n)$ occur with probability 1, and the groups of type E_6 , E_7 , and E_8 occur with probability 0.
- ▶ The global story is much different: because the ranks are bounded, the E_n groups play a significant rôle in the overall statistics, and occur with probability greater than 0.

7-branes in F-theory

- ▶ As another example, F-theory vacua are often interpreted as IIB string theory with 7-branes, and such 7-branes can be studied locally.

Conclusions

7-branes in F-theory

- ▶ As another example, F-theory vacua are often interpreted as IIB string theory with 7-branes, and such 7-branes can be studied locally.
- ▶ The essential data for an F-theory vacuum is the (complexified) IIB coupling, which is determined from the j -invariant of the family of elliptic curves

$$y^2 = x^3 + px + q,$$

where p and q are functions on the space X being used to (partially) compactify the IIB string.

7-branes in F-theory

- ▶ As another example, F-theory vacua are often interpreted as IIB string theory with 7-branes, and such 7-branes can be studied locally.
- ▶ The essential data for an F-theory vacuum is the (complexified) IIB coupling, which is determined from the j -invariant of the family of elliptic curves

$$y^2 = x^3 + px + q,$$

where p and q are functions on the space X being used to (partially) compactify the IIB string.

- ▶ The 7-brane wraps the discriminant locus $\{\Delta = 0\}$ of the above equation, where

$$\Delta = 4p^3 + 27q^2.$$

When X is local, we can assume that p and q have no common zeros.

$$\Delta = 4p^3 + 27q^2.$$

- ▶ But in the global case, if X has complex dimension at least 2, p and q are forced to have common zeros (except in very special cases, like product manifolds).

$$\Delta = 4p^3 + 27q^2.$$

- ▶ But in the global case, if X has complex dimension at least 2, p and q are forced to have common zeros (except in very special cases, like product manifolds).
- ▶ At a common zero of p and q , $\{\Delta = 0\}$ is itself singular (it has a “cusp” singularity) and the standard analysis of a 7-brane as a submanifold is not correct.

$$\Delta = 4p^3 + 27q^2.$$

- ▶ But in the global case, if X has complex dimension at least 2, p and q are forced to have common zeros (except in very special cases, like product manifolds).
- ▶ At a common zero of p and q , $\{\Delta = 0\}$ is itself singular (it has a “cusp” singularity) and the standard analysis of a 7-brane as a submanifold is not correct.
- ▶ In fact, there are a number of global issues with 7-branes in F-theory; in six dimensions, many of them can be related to anomaly cancellation in the effective six-dimensional theory (cf. [Grassi–DRM, math.AG/0005196](#)).

- ▶ Note that F-theory itself provides an alternative to pure D-brane constructions in this context.

- ▶ Note that F-theory itself provides an alternative to pure D-brane constructions in this context. The global data needed for F-theory vacua is specified by the family of elliptic curves (together with a bit more data pertaining to bundles on the branes),

- ▶ Note that F-theory itself provides an alternative to pure D-brane constructions in this context. The global data needed for F-theory vacua is specified by the family of elliptic curves (together with a bit more data pertaining to bundles on the branes), and methods of algebraic geometry can be used to probe the structure of these models in detail (as discussed in other talks at this conference).

Open strings and D-branes

- ▶ String vacua with D-branes (and orientifold planes) are ubiquitous in modern string phenomenology. But the global issues in the presence of D-branes are particularly subtle.

Conclusions

Open strings and D-branes

- ▶ String vacua with D-branes (and orientifold planes) are ubiquitous in modern string phenomenology. But the global issues in the presence of D-branes are particularly subtle.
- ▶ If the D-brane charges do not cancel, leaving a net Ramond–Ramond charge in the vacuum, there is a tadpole anomaly.

Open strings and D-branes

- ▶ String vacua with D-branes (and orientifold planes) are ubiquitous in modern string phenomenology. But the global issues in the presence of D-branes are particularly subtle.
- ▶ If the D-brane charges do not cancel, leaving a net Ramond–Ramond charge in the vacuum, there is a tadpole anomaly.
- ▶ This tadpole is suppressed in local models, since any excess Ramond–Ramond charge can escape to infinity. But it cannot be ignored in global models.

Open strings and D-branes

- ▶ String vacua with D-branes (and orientifold planes) are ubiquitous in modern string phenomenology. But the global issues in the presence of D-branes are particularly subtle.
- ▶ If the D-brane charges do not cancel, leaving a net Ramond–Ramond charge in the vacuum, there is a tadpole anomaly.
- ▶ This tadpole is suppressed in local models, since any excess Ramond–Ramond charge can escape to infinity. But it cannot be ignored in global models.
- ▶ Still, it has seemed reasonable to study different sources of D-brane charge in a local way, and assemble them later into a global model. This approach has recently been called into question.

- ▶ Typically, much of our information about local models comes not directly from analyzing string theory itself, but by twisting to get a topological theory and then studying that topological theory locally.

- ▶ Typically, much of our information about local models comes not directly from analyzing string theory itself, but by twisting to get a topological theory and then studying that topological theory locally.
- ▶ Recently, in work of [Walcher, arXiv:0712.2775 \[hep-th\]](#), and [Cook–Ooguri–Yang, arXiv:0804.1120 \[hep-th\]](#), it was realized that beyond tree-level, the open topological string theory itself is sensitive to the presence of a net Ramond–Ramond charge, when studied in the context of global models.

- ▶ Typically, much of our information about local models comes not directly from analyzing string theory itself, but by twisting to get a topological theory and then studying that topological theory locally.
- ▶ Recently, in work of [Walcher, arXiv:0712.2775 \[hep-th\]](#), and [Cook–Ooguri–Yang, arXiv:0804.1120 \[hep-th\]](#), it was realized that beyond tree-level, the open topological string theory itself is sensitive to the presence of a net Ramond–Ramond charge, when studied in the context of global models.
- ▶ That is, if one attempts to calculate open topological string amplitudes in a background with net Ramond–Ramond charge (using techniques pioneered by Walcher a few years ago), the answers reveal a new kind of anomaly in the topological string.

- ▶ This suggests that the purely local contributions to topological string amplitudes which have been computed in many situations will require unexpected corrections from other sectors of the background. It is not clear at present which conclusions about local physics escaped unchanged.

- ▶ This suggests that the purely local contributions to topological string amplitudes which have been computed in many situations will require unexpected corrections from other sectors of the background. It is not clear at present which conclusions about local physics escaped unchanged.
- ▶ In particular, model building which has relied on a decoupling of the D-brane and orientifold plane sectors of the theory may need to be reexamined.

Conifold transitions

- ▶ One situation in which the relationship of local and global approaches can be made clear is conifold transitions in open string theory, and the relationship to Gopakumar–Vafa large N duality.

Conifold transitions

- ▶ One situation in which the relationship of local and global approaches can be made clear is conifold transitions in open string theory, and the relationship to Gopakumar–Vafa large N duality.
- ▶ The local analysis starts with a 3-cycle in a local Calabi–Yau threefold X which is the vanishing cycle for an ordinary double point singularity (when the complex structure parameters are specialized), and the IIA string on $X \times M$ with a D6-brane wrapping the 3-cycle N times. Passing to the double point, and then blowing it up to obtain a 2-sphere, one finds a flux vacuum with N units of Ramond–Ramond flux on the 2-sphere.

Conifold transitions

- ▶ One situation in which the relationship of local and global approaches can be made clear is conifold transitions in open string theory, and the relationship to Gopakumar–Vafa large N duality.
- ▶ The local analysis starts with a 3-cycle in a local Calabi–Yau threefold X which is the vanishing cycle for an ordinary double point singularity (when the complex structure parameters are specialized), and the IIA string on $X \times M$ with a D6-brane wrapping the 3-cycle N times. Passing to the double point, and then blowing it up to obtain a 2-sphere, one finds a flux vacuum with N units of Ramond–Ramond flux on the 2-sphere.
- ▶ This transition has a lift to M-theory which was studied by [Atiyah–Maldacena–Vafa, hep-th/0011256](#), [Atiyah–Witten, hep-th/0107177](#), and others. The local M-theory space Y is a neighborhood of $S^3 \times S^3$, and the open string conifold transition is seen as a smooth deformation of M-theory vacua.

- ▶ In order to realize a conifold transition on a compact Calabi–Yau manifold, the collection of 3-cycles on which the transition is being made must have a homology relation (cf. [Greene–DRM–Strominger, hep-th/9504145](#)).

- ▶ In order to realize a conifold transition on a compact Calabi–Yau manifold, the collection of 3-cycles on which the transition is being made must have a homology relation (cf. [Greene–DRM–Strominger, hep-th/9504145](#)).
- ▶ In the context of the open string model, if we use the coefficients of the homology relation as the N_i on the various 3-cycles, then the net D6-brane charge is zero! Thus, the global requirement from geometry (in order to get a Kähler manifold after the transition) takes care of the tadpole anomaly in string theory as well as the open string anomaly discussed above.

- ▶ In order to realize a conifold transition on a compact Calabi–Yau manifold, the collection of 3-cycles on which the transition is being made must have a homology relation (cf. [Greene–DRM–Strominger, hep-th/9504145](#)).
- ▶ In the context of the open string model, if we use the coefficients of the homology relation as the N_i on the various 3-cycles, then the net D6-brane charge is zero! Thus, the global requirement from geometry (in order to get a Kähler manifold after the transition) takes care of the tadpole anomaly in string theory as well as the open string anomaly discussed above.
- ▶ How does this lift to M-theory? (cf. [DRM, to appear](#)).

- ▶ Given a compact Calabi–Yau manifold X and a collection of 3-cycles Z , the lift to M-theory should be a G2-manifold Y with a circle action that has fixed points along the 3-cycles $Z \subset Y$.

- ▶ Given a compact Calabi–Yau manifold X and a collection of 3-cycles Z , the lift to M-theory should be a G2-manifold Y with a circle action that has fixed points along the 3-cycles $Z \subset Y$.
- ▶ At present, unlike the local case, we do not have existence theorems for such G2-manifolds. However, the topological structure (and hence the classical moduli space) of our postulated G2-manifold can be analyzed. In general, one should consider both fixed points of a circle action, and allow the situation in which the Chern class of the circle bundle over $X - Z$ is non-trivial. (These are the flux vacua.)

- ▶ Given a compact Calabi–Yau manifold X and a collection of 3-cycles Z , the lift to M-theory should be a G2-manifold Y with a circle action that has fixed points along the 3-cycles $Z \subset Y$.
- ▶ At present, unlike the local case, we do not have existence theorems for such G2-manifolds. In general, one should consider both fixed points of a circle action, and allow the situation in which the Chern class of the circle bundle over $X - Z$ is non-trivial. (These are the flux vacua.)
- ▶ The result is that the G2-moduli space has an extra parameter for each 3-cycle in Z and an extra parameter for each 2-cycle in the support of the Chern class of the circle bundle.

- ▶ The result is that the G_2 -moduli space has an extra parameter for each 3-cycle in Z and an extra parameter for each 2-cycle in the support of the Chern class of the circle bundle.

- ▶ The result is that the G2-moduli space has an extra parameter for each 3-cycle in Z and an extra parameter for each 2-cycle in the support of the Chern class of the circle bundle.
- ▶ (These are “extra” when compared with the usual calculation of moduli for the case $X \times S^1$.) These extra parameters allow for the Atiyah et al. explanation of the local conifold transition to be present in the global moduli space.

- ▶ The result is that the G2-moduli space has an extra parameter for each 3-cycle in Z and an extra parameter for each 2-cycle in the support of the Chern class of the circle bundle.
- ▶ (These are “extra” when compared with the usual calculation of moduli for the case $X \times S^1$.) These extra parameters allow for the Atiyah et al. explanation of the local conifold transition to be present in the global moduli space. (Of course, we don’t know for sure that this happens since we cannot construct the G2-manifolds in question by this method.)

Lifting to M-theory

- ▶ Emboldened by our success for conifold transitions, let us suggest an approach to address global issues for arbitrary IIA vacua with both D-branes and orientifold planes: we propose that liftability to M-theory should be the criterion.

Lifting to M-theory

- ▶ Emboldened by our success for conifold transitions, let us suggest an approach to address global issues for arbitrary IIA vacua with both D-branes and orientifold planes: we propose that liftability to M-theory should be the criterion.
- ▶ We have in mind the class of models which involve both D6-branes and O6-planes.

Lifting to M-theory
